Climate from Climate Change Experiments Database

We developed a new, publicly available database for our analyses: the Climate from Climate Change Experiments (C3E) database, which is available at KNB (Ettinger and Wolkovich, 2017). This database allows us to explore the complex ways that climate is altered by active warming treatments, both directly and indirectly, across multiple studies. The database contains daily climate data collected between 1991 and 2014 from North American and European climate change experiments (Table S1, Figure 1 in the main text).

We carried out a full literature review to identify potential active field warming experiments to include in the database. To find these studies, we followed the methods and search terms of Wolkovich et al. (2012) for their Synthesis of Timings Observed in iNcrease Experiments (STONE) database (also available on KNB). We searched the Web of Science (ISI) for Topic=(warm* OR temperature*) AND Topic=(plant* AND phenolog*) AND Topic=(experiment* OR manip*). We restricted dates to the time period after the STONE database (i.e. January 2011 through March 2015). This yielded 277 new studies.

We wanted to focus on active warming studies only, because recent analyses indicate that active warming methods are the most controlled and consistent (Kimball, 2005; Kimball et al., 2008; Aronson and McNulty, 2009; Wolkovich et al., 2012). We therefore removed all passive warming studies from this list. In addition, a secondary goal of this database was to test hypotheses about mechanisms for the mismatch in sensitivities between observational and experimental phenological studies (Wolkovich et al., 2012). Because of this secondary goal, studies included in the database had to either 1) include more than one level of warming, or 2) manipulate both temperature and precipitation. (Some studies met both of these criteria.) These additional restrictions constrained the list to 11 new studies, as well as 6 of the 37 studies in the STONE database. We contacted authors to obtain daily (or sub-daily) climate data and the most accurate phenological data for these 17 sites, as well as two additional datasets offered to us over the course of our literature review. We received data from authors of 12 of these 19 studies or 67%. STONE received 16.7% of data directly (Wolkovich et al., 2012).

Details of Statistical Analyses and Results

Analysis of effects of time and space on local experimental climate

To test how treatment effects vary spatially (i.e. among blocks within a study) and temporally (i.e. among years within a study), we used data from the four studies in the C3E database that used blocked designs.

We fit linear mixed-effect models with mean daily soil temperature, minimum daily air temperature, and maximum daily air temperature as response predictors (Figure 3 in the main text). For temporal models, we included fixed effects of temperature treatment, year, and their interaction; random effects were site and block nested within site (intercept-only structure, Table S4). For spatial models, we included fixed effects of temperature treatment, block, and their interaction; random effects were site and year nested within site (intercept-only structure, Table S5). Both of these models excluded data from plots with precipitation treatments.

Analysis of effects of infrastructure on local experimental climate

To test how infrastructure affects local climate, we compared temperature and soil moisture data from the studies in the C3E database that monitored climate in two types of control plots: structural controls (i.e., ‘shams’ or ‘disturbance controls,’ which contained all the warming infrastructure, such as soil cables or infrared heating units but with no heat applied) and ambient controls with no infrastructure added. These five studies occurred at two sites: Duke Forest and Harvard Forest (Farnsworth et al., 1995; Clark et al., 2014; Marchin et al., 2015; Pelini et al., 2011). We fit linear mixed effects models by month with mean daily soil temperature, minimum and maximum daily air and soil temperature (Farnsworth et al. (1995) did not measure these predictors so there are only four different studies in these models), and soil moisture as response predictors. The fixed explanatory predictor was control type (sham or ambient). To allow for both mean differences in temperature and the effect of control to vary among sites and years, random effects were site and year nested within site, modeled with a random slopes and random intercept structure. We found that experimental structures altered above-ground and soil temperatures in opposing ways: above-ground temperatures were higher in the structural controls, compared with ambient conditions with no structures installed, whereas soil temperatures were lower in the structural controls compared with ambient soil (Figure 4 in the main text). In addition, soil moisture was lower in structural controls compared with ambient conditions. These general patterns were consistent across the different temperature models we fit (mean, minimum, and maximum soil and air temperatures), although the magnitude varied across months, as well as among studies. We show summaries from models fit to the entire year (Tables S6, S7, S8), as well as summaries from models fit to each month of data, as is shown in Figure 4 in the main text (Tables S9, S10, S11).

Analysis of effects of experimental warming on soil moisture

Of the twelve experiments in the C3E database, ten measured and reported soil moisture. To examine the effects of target warming treatment on soil moisture, we fit linear mixed effects models to data from these ten sites, excluding plots with precipitation treatments. We first fit a model with a fixed, continuous effect of target warming level (this ranged from 1.0 to 5.2 °C for these 10 studies). To account for methodological and other differences among site, we included site as a random effect, with day of year nested within site to account for the non-independent nature of measurements taken on the same day within sites. We used a random slope and intercept structure, to allow the effect of target warming to vary among sites (Table S12).

Since our previous analyses revealed that there can be reduced soil moisture due to the experimental structures themselves, we wanted to compare the effect of the structures themselves (i.e. in structural controls) to ambient levels, as well as to the warmed plots. We therefore fit a model with categorical fixed effects of “ambient,” “structural control,” and “warmed.” We again included site as a random effect, with day of year nested within site to account for the non-independent nature of measurements taken on the same day within sites, and used a random intercept structure (Table S13).

Table S3: Summary of linear mixed-effects models of how target warming treatment affects daily temperature range (DTR) for soil and above-ground temperatures, and for minimum and maximum above-ground temperatures in climate change experiments. We excluded data from plots with precipitation treatments from these analyses. Estimates (est.) are the intercept and coefficient for target warming from the model; se is the standard error for these estimates. The effect of target warming on observed warming was significant based on Type II Wald χ^2 tests of fixed effects for minimum air temperature ($\chi^2=45.25$, $df=1$, $p<0.001$) and maximum air temperature ($\chi^2=5.94$, $df=1$, $p=0.01$). Random effects were site ($n=8$) and year nested within site ($n=29$ year-site combinations), with a random intercept structure. Total number of observations=64,908 for max temperature model; and 81,016 for min temperature model.

	min above-ground temp.		max above-ground temp.	
predictor	est.	se	est.	se
intercept	7.12	0.91	19.18	1.58
target warming effect	0.57	0.11	0.67	0.16

Table S4: Analysis of variance table for temporal linear mixed-effects models of daily mean soil temperature, minimum above-ground temperature, and maximum above-ground temperature, fit by maximum likelihood. See Figure 3 in the main text. We list degrees of freedom (which are identical across response variables), test statistics, and p-values for Type III Wald χ^2 tests of fixed effects in the models. For all models, random effects were site ($n=6$) and block nested within site (intercept-only structure; $n=23$); total number of observations=17,177.

		mean soil temp.		min above-ground temp.		max above-ground temp.	
predictor	df	χ^2	p	χ^2	p	χ^2	p

Table S6: Summaries of linear mixed-effects models comparing effects of ambient versus structural controls on daily mean, minimum, and maximum soil temperature in climate change experiments across the year. Estimates (est.) are the intercept (representing ambient controls) and coefficient (representing structure effects) from the models; se is the standard error for these estimates. For these annual models, differences between control types were significant based on Type II Wald χ^2 tests of fixed effects for mean soil temperature ($\chi^2=5.53$, $df=1$, $p=0.01$) and minimum soil temperature ($\chi^2=3.87$, $df=1$, $p=0.05$), but not for maximum soil temperature ($\chi^2=2.07$, $df=1$, $p=0.15$). For all models, random effects of site ($n=5$ for mean model, $n=4$ for min and max models) and year nested within site ($n=21$ for mean model, $n=20$ for min and max models) were fit with a random slope and intercept structure; total number of observations= 48,860 for the mean model and 44,530 for the min and max models.

	mean soil temp.		min soil temp.		max soil temp.	
predictor	est.	se	est.	se	est.	se
intercept	11.89	1.42	10.81	1.48	13.92	1.61
structure effect	-0.57	0.24	-0.63	0.32	-0.54	0.38

Table S7: Summaries of linear mixed-effects models comparing effects of ambient versus structural controls on daily minimum and maximum air temperature in climate change experiments, across the year. Estimates (est.) are the intercept (representing ambient controls) and coefficient (representing structure effects) from the models; se is the standard error for these estimates. For these annual models, differences between control types were not significant based on Type II Wald χ^2 tests of fixed effects for minimum air temperature ($\chi^2=1.07$, $df=1$, $p=0.30$), nor for maximum air temperature ($\chi^2=0.01$, $df=1$, $p=0.91$). For both models, random effects of site ($n=4$) and year nested within site ($n=20$) were fit with a random slope and intercept structure; total number of observations= 44,085.

	min air temp.		max air temp.	
predictor	est.	se	est.	se
intercept	6.29	1.51	17.74	1.81
structure effect	0.36	0.35	0.02	0.21

Table S8: Summary of a linear mixed-effects model comparing effects of ambient versus structural controls on daily soil moisture in climate change experiments across the year. Estimates (est.) are the intercept (representing ambient controls) and coefficient (representing structure effects) from the models; se is the standard error for these estimates. For this annual model, the difference between control types was significant based on Type II Wald χ^2 tests of fixed effects ($\chi^2=89.95$, $df=1$, $p<0.001$). Random effects of site ($n=5$) and year nested within site ($n=21$ year-site combinations) were fit with a random slope and intercept structure; total number of observations= 44,468.

Table S11: Summaries of linear mixed-effects models, fit to each month comparing effects of ambient versus structural controls on soil moisture, fit to each month separately, consistent with Figure 4 in the main text. Estimates (est.) are the intercept (representing ambient controls) and coefficient (representing structural effects) from the models; se is the standard error for these estimates. We list test statistics, and p-values for Type II Wald χ^2 tests of fixed effects; df=1 for all models. Random effects of site (n=4) and year nested within site (n=18 year-site combinations) were fit with a random slope and intercept structure; total number of observations was 3,829.

mon	predictor	est.	se	χ^2	p
01	intercept	22.58	3.23	59.24	<0.001
	structure effect	-2.77	0.36		
02	intercept	22.10	3.24	16.78	<0.001
	structure effect	-2.54	0.62		
03	intercept	23.58	2.43	8.3	0.004
	structure effect	-2.48	0.86

Table S12: Summary of a linear mixed-effects model of how target warming treatment affects soil moisture in climate change experiments. We excluded data from plots with precipitation treatments from this analysis. Estimates (est.) are the intercept and coefficient for target warming from the model; se is the standard error for these estimates. The effect of target warming was marginally significant, based on Type II Wald χ^2 tests of the fixed effect ($\chi^2=3.49$, $df=2$, $p=0.06$). Random effects were site ($n=10$) and day of year nested within site ($n=2434$ day of year-site combinations), with a random slope and intercept structure. Total number of observations was 72,730

	est.	se
intercept	0.21	0.02
target	-0.00	0.00

Table S13: Summary of a linear mixed-effects model comparing soil moisture in experimentally warmed plots to two different control types, structural and ambient controls. We excluded data from plots with precipitation treatments from this analysis. Estimates (est.) are the intercept (representing mean moisture in ambient controls) and coefficients from the from the model (i.e. differences between the ambient) for structural controls and warmed plots (pooled across all target warming levels); se is the standard error for these estimates. There were significant differences among warming types based on Type II Wald χ^2 tests of the fixed effect ($\chi^2=7229.01$, $df=2$, $p<0.001$). Random effects were site ($n=10$), year nested within site ($n=35$ site-year combinations), and day of year nested within year (7,979 day of year-year-site combinations) with a random intercept structure. Total number of observations was 72,730

	est.	se
intercept	0.22	0.01
structure effect	-0.02	0.00
warmed effect	-0.03	0.00
